

# Fertilization of *Dioscorea rotundata* with poultry manure: effects on nutrient dynamics and nutrient use efficiencies

Andres C., Diby L.N., Hgaza V.K. and Frossard E.

## Background

- Yam: tropical tuber crop
- High food and market values
- 1<sup>st</sup> crop after clearing forest
- Requires high soil fertility
- Tradition: no external fertilizer input
- Population growth: pressure on land ↑

## Problem

- Yields far below potential
- Suitable land becoming scarce
- Need for sustainable cropping systems
- Experiment with poultry manure**
- Objective: study effects of PM, fertilizer and their combination on productivity

**Similar effects of poultry manure (PM) and mineral fertilizer suggest that PM is a cheap and effective alternative to fertilizers for yam production!**

## Experiment

- *D. rotundata* cv. TDr 89/02461
- Low fertility savanna soil
- Central Côte d'Ivoire, 2010
- 7 fertilizer treatments:
  - Control (no fertilizer)
  - 3 **mineral fertilizer treat.**, different N applications (0 – 60 – 120 kg N ha<sup>-1</sup>)
  - 2 **organic fertilizer treat.**, different N applications (60 – 120 kg N ha<sup>-1</sup>)
  - Combination **mineral/organic** (60 & 60 kg N ha<sup>-1</sup>)
- Measurements:
  - Soil analysis before and after cropping
  - Elements Ca, Mg, **N**, P and **K** in PM, soil and plant

## Results

- N fertilization enhanced N uptake (Figure 1) and prolonged role of leaves as sink for N (Figure 2) but favored shoot over tuber growth
- Mineral fertilizer acted indirectly on yield probably by stimulating soil microbes
- PM had other beneficial effects on crop development than provision of N
- physiological advance of plants and highest yields in PM treatments

## Outlook

**Future yam research needs to integrate both participative on-farm, and more fundamental on-station trials**
