

# Farm gate nutrient budgets for organic farming

## Problem

Nutrient imbalances are often not noticed on organic farms. However, nutrient deficits can deplete the soil in the long-term and therefore reduce soil fertility.

## Solution

Farm gate nutrient budgets are an easy and efficient tool to assess the main nutrient flows in and out of the farm. They can reveal whether there is a nutrient surplus or deficit.

## Outcome

The outcome is a farm gate nutrient budget for one or up to three years. Nutrient inputs can be adjusted to achieve a balanced nutrient budget.

## Practical recommendations

To calculate the farm gate nutrient budget, all nutrient inputs and outputs need to be quantified. The difference between them shows if there is an imbalance or not (Figure 1).

The following groups are classified as nutrient inputs: imported feed, fertilizer, soil amendments, seeds, and N-fixation by legumes. For all imported goods, the nutrients can be calculated by multiplying the amount with the given nutrient content. The N-fixation is calculated based on the yield of the leguminous crops. If yields are not available, typical N-fixation values per hectare are given for different cropping densities.

All sold products or by-products are classified as nutrient outputs. The nutrients can also be calculated by multiplying the amount with the given nutrient content.

The Excel tool (Figure 2) is an easy way to calculate a nutrient budget. It provides data on nutrient contents of common inputs and outputs, and it calculates the resulting N-fixation. The user only needs to enter the farm specific data. The tool will then calculate the farm gate nutrient budget. The Excel tool is available in English and German online on Organic eprints.

## Applicability box

### Input used

- Copper
- Mineral oil
- Fertilisers
- Anthelmintics
- Antibiotics
- Vitamins

### Geographical coverage

Temperate climate zones

### Application time

After each cropping season / year

**Required time** 1-3 hours depending on quality of farm documentation

### Period of impact

Future nutrient management

### Equipment

Good farm documentation, computer

### Best in

All types of organic farms

## On-farm application

### System approach and evaluation

Farm gate balancing is a useful approach for understanding the farming system. If the farm gate nutrient budget results in a high deficit for any nutrient, this means that the soil will be mined on the long-term. High nutrient surpluses, on the other hand, can result in nutrient losses with a negative impact on the environment (e.g. leaching). However, nutrient budgets must also be seen in relation to the soil nutrient status, e.g. a positive budget may be desirable to raise nutrient status of a depleted soil.

**RELACS:** 'Replacement of Contentious Inputs in Organic Farming Systems' (RELACS) builds on results of previous research projects and takes far-advanced solutions forward. As a system approach to sustainable agriculture, organic farming aims to effectively manage ecological processes whilst lowering dependence on off-farm inputs. The RELACS partners will evaluate solutions to further reduce the use of external inputs and, if needed, develop, and adopt cost-efficient and environmentally safe tools and technologies.
