

# Nettle cultivation for feeding poultry

## Problem

Feeding poultry with regional and fully organic components, in line with animal needs, is still very difficult to achieve in many parts of Europe. The supply of sulphur-containing amino acids (e.g., methionine) is especially challenging.

## Solution

In the search for protein-rich feed components, the cultivation of nettles was investigated. Stinging nettles were traditionally fed to pigs and poultry, partly because of its high protein content.

The cultivation of stinging nettles was tested in an experiment on two trial plots. The sowing was done by purchased seeds (no-till) and by vegetative propagation (stolons). During growing, different fertiliser applications were tested. Consisting of chicken manure and sulphur (Kieserite 25 % MgO, 50 % SO<sub>3</sub>) in autumn and spring to provide information on the influence of sulphur applications on methionine concentration.

## Applicability box

### Theme

Pigs, Broilers, Layers, Feeding and ration planning, Processing and handling of harvested feed

### Context

Cultivation methods and fertilisation options for nettle as a native protein feed.

### Application time

Perennial cultivation

### Required time

Crop requires a lot of time for establishment, irrigation and feeding before harvesting and processing

### Period of impact

Use over several years

### Equipment

Irrigation, harvesting, chopping and, drying machinery required

### Best in

Health-promoting and protein-rich domestic feed.

## Benefits

The on-farm cultivation of nettles for feeding purposes could be an element in feeding monogastric animals. The health-promoting effect of nettles should not be underestimated.

## Practical recommendation

- Purchased seeds had a poor germination. Propagation from cuttings (stolons) is more effective.
- Cultivate with 50 cm between and 30 cm between plants (see figure 1).
- The stinging nettle has a high nitrogen demand so application of fertiliser is recommended before planting and after the first cut.
- The crop should not be harvested too late, in order to achieve the highest leaf proportion (see figure 2).
- Any influence of fertiliser application could not be determined. Clearly visible is the influence of the soil temperature. Later cuts provided significantly better methionine yields.
- Analysis of the pure leaf mass yielded good methionine values up to 4.52 g/kg DM<sub>88</sub> (see table 1). However, the ratio of methionine to lysine, at 0.32
- Compared to small-grained legumes, nettle cultivation is very costly and the additional methionine yields are too low when considering the extra cost.

**Table 1: analysis nettle leaves**

Date Analysis	19.07.08
<b>Nutrients [g/kg]</b>	
Dry matter (DM)	880
Crude ash	161
Crude protein	289
Crude fibre	83
Crude fat	19
Sugar	38
<b>Energy values [MJ]</b>	
Metabolizable energy (ME)	5.61
<b>Amino acids [g/kg DM]</b>	
Lysine	14.34
Methionine	4.52
Threonine	11.41
Tryptophan	2.85

**OK-Net EcoFeed:** This practice abstract was elaborated in the Organic Knowledge Network on Monogastric Animal Feed project. The project is running from January 2018 to December 2020. The overall aim of OK-Net EcoFeed is to help farmers, breeders and the organic feed processing industry in achieving the goal of 100% use of organic and regional feed for monogastrics.
